(54) Slow-release pharmaceutical composition.

(57) Slow-release pharmaceutical compositions which comprise at least one of the following: adenine, cystine and tyrosine in combination with at least one pharmaceutically active substance are disclosed. The slow-release pharmaceutical compositions which may be tablets, granules implants, capsules, troches etc. can either slowly release their active substances over time or release the active substances at a predetermined time after their administration. The slow-release pharmaceutical composition may be used with practically all types of drugs irrespective of whether they are water-soluble or slightly water-soluble, including hypotensives, antipyretic analgesic antiinflammatories, immunoregulators, adrenocortical hormones, antidiabetic agent, vasodilators, cardiotonics, antiarrhythmic agents, anti-arteriosclerotic agents, and antidotes.

EP 0 284 039 A2

SLOW-RELEASE PHARMACEUTICAL COMPOSITION

While many compounds are known to be useful as pharmacologically active substances, some of them have relatively short biological half lives and must be administered several times a day to exhibit their full action.

However, a decrease in the number of administrations will not only reduce the burden on the patient but will also increase his compliance and thus provide greater therapeutic effects. To meet this requirement, medicines must release their active ingredients slowly so that they maintain effective levels in the blood for a prolonged period of time. In addition, if the active substance of a drug can be released at a predetermined time after its administration, it is possible to allow a larger amount of the active substance to be released at a particular site of an organ such as the digestive tract, thereby producing enhanced therapeutic effects.

Therefore, the principal object of the present invention is to provide a pharmaceutical composition (pharmaceutical agent) which is so designed that it will either slowly release its active substance or release the active substance, at a predetermined time after its administration.

Various techniques have been proposed for preparing slow-release pharmaceutical compositions that are capable of retaining the concentrations of their active substances in the blood for a prolonged period of time. Most of the slow-release pharmaceuticals so far proposed employ a variety of high-molecular weight materials which include: hydroxypropyl cellulose, hydroxypropyl methyl cellulose, hydroxypropyl methyl cellulose phthalate, pullulan, gelatin, collagen, casein, agar, gum arabic, dextrin, ethyl cellulose, methyl cellulose, chitin, chitosan, mannan, carboxymethylethyl cellulose, sodium carboxymethyl cellulose, polyethylene glycol, sodium alginate, poly(vinyl alcohol), cellulose acetate, poly(vinylpyrrolidone), silicone, poly(vinyl acetal) diethylamino acetate and albumin [see Sustained and Controlled Release Drug Delivery Systems, Marcel Dekker, Inc., 1978; Yakkyoku (Pharmacy), vol. 35, No. 2, pp 575 - 583, 1984; and Japanese Patent Public Disclosure No. 62521/1984].

The use of the above-listed high-molecular weight materials in manufacturing slow-release pharmaceuticals involves several problems: (1) many high-molecular weight materials, particularly those which are soluble in water, have such a high moisture content that the pharmacologically active substances incorporated therein are liable to suffer decomposition, such as by hydrolysis, and often fail to withstand prolonged storage; (2) high-molecular weight materials have a certain distribution of their molecular weight and their molecular weight distribution and average molecular weight generally differ from one to another notwithstanding the existence of certain limits to be complied with and, therefore, the slow-release pharmaceuticals employing such high-molecular weight materials will experience considerable variations in drug dissolution rate no matter how strict the quality control is during the manufacturing process; (3) some of the slow-release pharmaceuticals employing high-molecular weight materials are used by being implanted into the human body, but many high-molecular weight materials are not decomposed in the human body at all or are decomposed only slightly, so they must be removed from the human body after they have liberated the pharmaceutically active substance; even the high-molecular weight materials that are decomposable in the human body are in most cases dependent upon the presence of decomposition enzymes if the rate of their decomposition is to be satisfactory, and this also applies to the rate of release of the active substance; furthermore, even the decomposable high-molecular weight materials are not completely decomposed to monomers and there is a high possibility that only a part of them will be decomposed, most of them remaining as polymers and are absorbed by tissue to become potential antigens which can cause an anaphylactic shock [see Seiyaku Kogyo (Pharmaceutical Factory), vol 3, No. 10, pp. 552 - 557 (1983); and Kagaku no Ryoiki (Region of Chemistry), Special Issue, No. 134, pp. 151 - 157, Nankodo]; (4) in slow-release pharmaceuticals of the matrix type and those wherein the active substances (i.e., drugs) are released through a semipermeable membrane, the rate of drug release is so highly dependent on the solubility of the drug that such types of slow-release pharmaceuticals are not suitable for use with sparingly soluble drugs; and (5) pharmaceuticals with a coating of water-insoluble high-molecular weight substances are unable to release the active substance at a predetermined time after their administration; water-soluble high-molecular weight substances will immediately swell by an infinite degree and are unable to inhibit the drug release for a prolonged period; enteric high-molecular weight substances are unable to release the drug at pHs below 5.0 - 5.5 but will immediately release it at higher pHs, and hence are unable to perform time-dependent and not pH-dependent, control of the drug release.

The present inventors conducted various studies to develop a process for preparing a slow-release pharmaceutical composition that is free from the aforementioned problems of the prior art products. As a result, the present inventors unexpectedly found that the duration of the sustained release of a pharmaceutically active substance can be extended or its release at a predetermined time after drug administration can

be realized by employing at least one "slow-release rendering additive" selected from the group consisting of adenine, cystine and tyrosine, all being low-molecular weight substances. Cystine and tyrosine occur in isomeric forms but their effectiveness is independent of whether they are in the D-, L- or DL-form.

Fig. 11 shows the results of a Fuchs test conducted on the fine granules prepared in Example 12 (-O-) and MgO alone (--O--); and

Fig. 12 shows the time-dependent change in reticulocyte counts after burial of the implants prepared in Example 13 (-) and erythropoietin in physiological saline (---).

The slow-release pharmaceutical composition of the present invention is prepared by the following procedure: predetermined amounts of a pharmaceutically active substance and an excipient are weighed; a predetermined amount of a selected "slow-release rendering additive" is weighed and the individual components are mixed by a routine method. The amount of the pharmaceutically active substance used varies with factors such as the type and dosage form of the pharmaceutical composition and is usually less than 90%, preferably less than 75%, of the total weight of the composition. The amount of the "slow-release rendering" additive to be incorporated is usually more than 2%, preferably more than 5%, of the total weight of the composition.

The use of an excipient is optional.

Preferable excipients are lactose, mannitol, inositol, calcium citrate, dibasic calcium phosphate, fumaric acid, hardened oils, corn oil, sesame oil, stearic acid, etc. The amount of excipient, if one is to be used at all in combination with the "slow-release rendering" additive is usually in the range of from 0 to 95%, preferably from 0 to 80%, of the total weight of the composition.

The slow-release pharmaceutical composition of the present invention may be used with practically all types of drugs irrespective of whether they are water-soluble or slightly water-soluble, including hypotensives, antipyretic analgesic antiinflammatories, immunoregulators, adrenocortical hormones, antidiabetic agents, vasodilators, cardiotonics, antiarrhythmic agents, anti-arteriosclerotic agents and antidotes.

The term "slightly water-soluble" when applied to drugs means that their water solubility affects their absorption by the human body. With slightly soluble drugs that have water solubilities of no more than 0.1% [Nakai and Hanano, "Seizaigaku (Pharmaceutics)", p. 296, September 20, 1974, Nanzando], good slow-releasing effects can be attained by grinding the drugs to particles having an average size of no more than 10 μ m and using hydroxypropyl cellulose of low substitution degree and hydroxypropyl cellulose as excipients. Drug particles having an average size of no more than 10 μ m can be prepared by using a jet mill grinder (Model FS-4 of Seishin Enterprise Co., Ltd.)

To the mixed powder thus prepared, containing the pharmaceutically active substance, a "slow-release rendering" additive and optionally an excipient, a lubricant such as magnesium stearate, calcium stearate or talc and any other necessary components are added and the resulting mixture is compressed into tablets. If desired, the mixture may be worked into a dosage form suitable for implanting in the human body.

The mixed powder may also be blended with sucrose, a fragrance, a colorant and any other appropriate components and the resulting blend is then compressed to form troches of predetermined phases. If desired, the blend may be formulated as a pharmaceutical composition for buccal administration.

A layer (A) containing a pharmaceutically active substance may be placed on another layer (B) containing no such active substance and the two layers are then compressed together to form a double-layered tablet which achieves enhanced delivery of the effective substance after a given period of time. Two modifications of this multiple-layered tablet are as follow: a tablet which is prepared by compressing a layer having the composition specified by the present invention and a fast-release layer containing the same pharmaceutically active substance that is present in the first layer; and a tablet prepared by compressing the following three layers together, the first layer having the composition specified by the present invention, the second layer containing at least one "slow-release rendering" additive, and the third layer being a fast-

release layer containing a pharmaceutically active substance which is the same as that present in the first layer.

The mixed powder described above may be blended with an appropriate binder, such as hydroxypropyl cellulose, hydroxypropyl methyl cellulose or cornstarch, dissolved in either water or an organic solvent, and the blend is granulated, dried and classified (e.g. sieved) to obtain granules. If desired, granules having this composition may be mixed with fast-release granules containing the same pharmaceutically active substance. Slow-release enteric granules may be prepared by coating the first granulate with enteric bases such as hydroxypropyl methyl cellulose phthalate and carboxymethylethyl cellulose. Said first granules may be coated with water-insoluble bases and the so coated granules may optionally be mixed with fast-release granules containing the same pharmaceutically active substance. The fast-release granules containing a pharmaceutically active substance may be coated with at least one "slow-release rendering" additive to convert them into slow-release granules that release the drug at a predetermined time after their administration.

If desired, these slow-release granules may be compressed to form slow-release tablets; mixtures of said granules with water-insoluble bases may be compressed into tablets, and the so formed tablets may be coated with enteric bases or water-insoluble bases. These tablets may be provided with a sugar coating which may optionally contain a pharmaceutically active substance that is of the same type as incorporated in the center of the tablets. Core/shell type slow-release tablets may be prepared by compressing the aforementioned tablets after they have been coated with a fast-release composition containing the same pharmaceutically active substance. In this case, a coat of at least one "slow-release rendering" additive may be layered between the core of the tablet and the shell comprising the fast-release composition. The fast-release core tablet containing a pharmaceutically active substance may be coated first with a layer containing at least one "slow-release rendering" additive, then with an enteric base such as hydroxypropylmethyl cellulose phthalate or carboxymethylethyl cellulose to form an enteric tablet that releases the active substance at a predetermined time after drug administration.

Any type of the aforementioned granules may be encapsulated to form capsules. If desired, the aforementioned slow-release granules may be incorporated in suppository bases to form slow-release suppositories. Alternatively, slow-release suppositories may be prepared by coating the aforementioned slow-release tablets with suppository bases.

The "slow-release rendering" additive to be incorporated in the slow-release pharmaceutical composition of the present invention may be used either independently or in mixtures of any appropriate proportions. By adding water-soluble materials such as lactose, mannitol and inositol, or compounds such as calcium citrate and dibasic calcium phosphate that are either water-soluble or highly wettable with water, the dissolution of a pharmaceutically active substance can be promoted. Conversely, the dissolution of the active substance can be retarded by adding oils such as corn oil and sesame oil or waxes such as hardened oils and stearic acid. The dissolution rate of the active substance can be varied with the pH of the environment used by adding an enteric base such as hydroxypropylmethyl cellulose phthalate or carboxymethylethyl cellulose, or an organic acid such as fumaric acid. It is also possible to maintain a substantially constant dissolution rate at all pHs of the environment.

The slow-release pharmaceutical composition of the present invention releases its active substance as the "slow-release rendering" additive is slowly lost, so that the pharmaceutically incorporated active substance may be water-soluble or sparingly water-soluble and is not limited to any particular type.

It should of course be understood that colorants, flavoring agents, stabilizers and any other appropriate additives may be added as required to the slow-release pharmaceutical composition of the present invention to use.

The present invention is hereunder described in greater detail with reference to working examples and a comparative example, to which the scope of the invention is by no means limited.

Example 1

		lower layer (mg)	middle layer (mg)	upper layer (mg)
5	<u>Layered tablet</u>			
	Nicorandil	7	-	3
	Adenine	52.6	29.8	-
10	Lactose	-	-	16.8
	Crystalline cellulose	-	-	10
	Calcium stearate	0.4	0.2	0.2
15	Total	60	30	30

Seven grams of Nicorandil, 52.6 g of adenine and 0.4 g of calcium stearate were weighed and mixed well in a polyethylene bag to form a mixed powder A.

20 In a separate step, 29.8 g of adenine and 0.2 g of calcium stearate were weighed and mixed well in a polyethylene bag to form a mixed powder B.

Thereafter, 3 g of Nicorandil, 16.8 g of lactose, 10 g of crystalline cellulose and 0.2 g of calcium stearate were weighed and mixed well in a polyethylene bag to form a mixed powder C.

25 Multilayer tableting was performed on a single-punch machine equipped with a die (7 mm \varnothing) and flat-faced punches: first, 60 mg of the mixed powder A was placed in the die and precompressed lightly; 30 mg of the mixed powder B was placed on the first fill and lightly precompressed; thereafter, 30 mg of the mixed powder C was placed on the second fill and compressed with a total pressure of about 1 ton.

The resulting multiple-layered tablets had the dissolution profile depicted in Fig. 1 that was obtained by conducting a dissolution test with an apparatus of the type specified in "Method I (rotary basket method)", 30 Japanese Pharmacopoeia, 11th rev.; 500 ml of Fluid 2 (pH = 6.8) was used as a testing fluid and the basket was rotated at 100 rpm.

Example 2

35	<u>Tablet</u>	
	Thiamazole	5 (mg)
40	L-tyrosine	70
	Adenine	70.5
	Cornstarch	2.5
45	Magnesium stearate	2
	Total	150

50 Seventy grams of L-tyrosine and 70.5 g of adenine were mixed well in a mortar to form a triturate, which was well blended with 20.8 g of a 12% cornstarch paste. The blend was granulated after passage through a 35-mesh sieve, dried at 50°C in a tray dryer for 5 hours and sieved through a 32-mesh sieve to obtain granules. Five grams of Thiamazole, 143 g of the granules and 2 g of magnesium stearate were weighed and mixed well in a polyethylene bag.

55 The mix was charged into a single-punch tableting machine equipped with a die (8 mm \varnothing) and flat-faced punches, and compressed with a total pressure of 1.2 tons to make tablets each weighing 150 mg.

Comparative Example 1Tablet

5	Thiamazole	5 (mg)
	Lactose	121
	Crystalline cellulose	20
10	Cornstarch	2
	Magnesium stearate	2
	<hr/>	
15	Total	150

Lactose (121 g) and 12% cornstarch paste (16.7 g) were blended well in a mortar. The blend was granulated after passage through a 35-mesh sieve, dried at 50°C in a tray dryer for 5 hours, and sieved through a 32-mesh sieve to obtain granules. Five grams of Thiamazole, 123 g of the granulation, 20 g of crystalline cellulose and 2 g of magnesium stearate were weighed and mixed well in a polyethylene bag.

The mix was charged into a single-punch machine equipped with a die (8 mm \varnothing) and flat-faced punches, and compressed with a total pressure of 1.2 tons to make tablets each weighing 150 mg.

The tablets prepared in Example 2 and Comparative Example 1 had the dissolution profiles shown in Fig. 2. The data in Fig. 2 were obtained by conducting dissolution tests with an apparatus of the type shown in "Method II (puddle method) of Dissolution Test", Japanese Pharmacopoeia, 11th rev.; 500 ml of Fluid 2 (pH = 6.8) was used as a testing fluid and the puddle was rotated at 100 rpm.

Example 3Granules (per 500 mg)

30	Theophylline	150 (mg)
35	DL-Cystine	330
	Corn oil	10
	Carboxymethyl cellulose	10
40	<hr/>	
	Total	500

A hundred and fifty grams of Theophylline and 330 g of DL-cystine were weighed and mixed well in a mortar. To the resulting triturate, a mixture of 10 g of corn oil with 100 g of a 10% solution of carboxymethylethyl cellulose in ethanol was added and blended well. The blend was granulated in a rotary granulator equipped with a net (1.2 mm \varnothing), dried at 45°C in a tray dryer for 6 hours, and sieved through a 10-mesh sieve to make granules.

The granules had the dissolution profile shown in Fig. 3 that was obtained by conducting a dissolution test on 200 mg of the granules with an apparatus of the type specified in "Method I (rotary basket method) of Dissolution Test", Japanese Pharmacopoeia, 11th rev.; 500 ml of Fluid I (pH = 1.2) was used as a testing fluid and the basket was rotated at 100 rpm.

Talc	7

Subtotal	40
----------	----

Total	340
-------	-----

Fourteen grams of Picibanil[®] (freeze-dried powder), 31.5 g of lactose and 50 g of hydroxypropyl cellulose of low substitution degree were weighed and mixed well in a mortar. To the triturate, 40 g of a 10% aqueous solution of hydroxypropyl cellulose was added and the individual components were blended together. The blend was sieved through a 16-mesh screen, granulated, dried by being left in a silica gel filled desiccator for one day, and sieved through a 12-mesh sieve. The granulate (99.5 g) and calcium stearate (0.5 g) were mixed well in a polyethylene bag.

The mix was charged in a single-punch tableting machine equipped with a die (7 mm \varnothing) and punches (R = 10 mm), and compressed with a total pressure of 0.8 tons to make core tablets each weighing 100 mg.

A hundred grams of adenine, 50 g of L-cystine and 45 g of dibasic calcium phosphate were weighed and mixed well in a mortar. To the triturate, 40 g of a 10% aqueous solution of hydroxypropylmethyl cellulose was added and the individual components were blended together. The blend was sieved through a 20-mesh screen, granulated, dried at 50°C in a tray dryer for 5 hours, and sieved through a 16-mesh sieve. The granule (199 g) and calcium stearate (1 g) were intimately mixed in a polyethylene bag to make granules for the outer layer.

A die (10 mm \varnothing) and punches (R = 14 mm) were set on a single-punch tableting machine and 70 mg of the granules for the outer layer were charged into the die. The core tablet was placed in the center of the

granules and another 130 mg of the granules for the outer layer was charged into the die. The charge was compressed with a total pressure of about 1.5 tons to make double-layered tablets.

Triacetin (3 g) and talc (7 g) were dissolved in 140 g of water under agitation. Thereafter, 100 g of Eudragit® L30D 55 (30% dispersion) was added to make an enteric coating solution.

Thirty grams of the double-layered tablets (ca. 100 in number) and 200 g of preliminarily prepared dummy tablets (9 mm ϕ , R = 13 mm; weight of each tablet, 210 mg) were charged into a Flow Coater (UNI-GLATT® of Okawara Mfg. Co., Ltd.) and a coating operation was performed by standard procedures until each of the double-layered tablets was coated with 40 mg of the previously prepared enteric coating solution.

The so prepared double-layered tablets with an enteric coating had the dissolution profiles shown in Table 1. The data in Table 1 was obtained by conducting a microbial release test on the tablets with an apparatus of the type specified in "Method II (puddle method) of Dissolution Test", Japanese Pharmacopoeia, 11th rev.; 500 ml each of Fluid 1 (pH = 1.2) and Fluid 2 (pH = 6.8) was used as testing fluids and the puddle was rotated at 100 rpm.

Microbial release was established by microscopic observation of the testing fluids.

Table 1

Testing fluid \ Time (hr)	0.5	1	2	3	4	5
I	-	-	-	-	-	-
II	-	-	-	-	+	+

+ : Visible microbial cells

Example 5

Layered tablet	upper layer (mg)	lower layer (mg)
Phenacetin	50	100
Lactose	37	-
Hydroxypropyl cellulose of low substitution degree	10	-
L-Tyrosine	-	93
Hydroxypropyl cellulose	2	5
Calcium stearate	1	2
Total	100	200

Phenacetin and L-tyrosine were ground with a jet mill (Model FS-4 of Seishin Enterprise Co., Ltd.) into particles having an average size of 2 - 3 μ m (the particles obtained by grinding with a jet mill are hereinafter referred to as "jet mill ground powder").

Fifty grams of Phenacetin (jet mill ground powder), 37 g of lactose and 10 g of hydroxypropyl cellulose of low substitution degree were weighed and mixed well in a mortar. To the triturate, 20 g of a 10% aqueous solution of hydroxypropyl cellulose and 12 g of water were added and blended well. The blend was ground after passage through a 14-mesh sieve, dried at 50°C in a tray dryer for 5 hours, and sieved through a 10-mesh sieve. To 99 g of the granules 1 g of calcium stearate was added and the two were mixed well in a polyethylene bag. The resulting granules were designated granules (a).

A hundred grams of Phenacetin (jet mill ground powder) and 93 g of L-tyrosine (jet mill ground powder) were weighed and mixed well in a mortar. To the triturate, 50 g of a 10% aqueous solution of hydroxypropyl cellulose and 44 g of water were added and blended well. The blend was granulated after passage through a 14-mesh sieve, dried at 50°C in a tray dryer for 5 hours, and sieved through a 10-mesh sieve. To 198 g of the granules, 2 g of calcium stearate was added and the two were mixed well in a polyethylene bag. The resulting granules were designated granules (b).

Multi-layer tableting was performed on a single-punch machine equipped with a die (10 mm \varnothing) and flat-faced punches: first, 200 mg of granules (b) were placed in the die and precompressed lightly; then 100 mg of granules (a) were placed on the first fill and compressed with a total pressure of about 2 tons.

The resulting double-layered tablets had the dissolution profile depicted in Fig. 4 that was obtained by conducting a dissolution test with an apparatus of the type specified in "Method II (puddle method) of Dissolution Test", Japanese Pharmacopoeia, 11th rev.; 900 ml of distilled water was used as a testing fluid and the puddle was rotated at 100 rpm.

Example 6

Tablet

Griseofulvin	125 (mg)
L-Tyrosine	40
Fumaric acid	126
Hydroxypropyl cellulose	6
Magnesium stearate	3
<hr/>	
Total	300

A hundred and twenty-five grams of griseofulvin (jet mill ground powder; average particle size, 1 - 2 μ m), 40 g of L-tyrosine (jet mill ground powder; average particle size, 2 - 3 μ m) and 126 g of fumaric acid (jet mill ground powder; average particle size, 4 - 5 μ m) were weighed and mixed well in a mortar. To the triturate, 60 g of a 10% aqueous solution of hydroxypropyl cellulose and 62 g of water were added and blended well. The blend was granulated after passage through a 14-mesh sieve, dried at 60°C in a tray dryer for 3 hours, and sieved through a 10-mesh sieve. To 297 g of the granules 3 g of magnesium stearate was added and the two were mixed well in a polyethylene bag.

The mix was charged into a single-punch tableting machine equipped with a die (10 mm \varnothing) and flat-faced punches, and compressed with a total pressure of about 2 tons to make tablets each weighing 300 mg.

Comparative Example 2Tablet

Griseofulvin	125 (mg)
Lactose	166
Hydroxypropyl cellulose	6
Magnesium stearate	3
Total	300

A hundred and twenty-five grams of griseofulvin (jet mill ground powder; average particle size, 1 - 2 μm) and 166 g of lactose were weighed and mixed well in a mortar. To the triturate, 60 g of a 10% aqueous solution of hydroxypropyl cellulose and 14 g of water were added and blended well. The blend was granulated after passage through a 14-mesh sieve, dried at 60°C in a tray dryer for 3 hours, and sieved through a 10-mesh sieve. To 297 g of the granules, 3 g of magnesium stearate were added and the two were mixed well in a polyethylene bag.

The mix was charged into a single-punch tableting machine equipped with a die (10 mm \varnothing) and flat-faced punches, and compressed with a total pressure of about 2 tons to make tablets each weighing 300 mg.

The tablets prepared in Example 6 and Comparative Example 2 had the drug release profiles shown in Fig. 5 (griseofulvin was insoluble in water, so the state of dispersion of its fine particles was evaluated by turbidity measurement). The data in Fig. 5 was obtained by conducting a release test with an apparatus of the type specified in the "Method of Disintegration Test", Japanese Pharmacopoeia, 11th rev.; 1,000 ml of distilled water was used as a testing fluid and the glass tubes containing the test fluid were moved up and down 20 times a minute.

Example 7Tablet

Griseofulvin	125 (mg)
L-Tyrosine	166
Hydroxypropyl cellulose	6
Magnesium stearate	3
Total	300

A hundred and twenty-five grams of griseofulvin (jet mill ground powder; average particle size, 1 - 2 μm) and 166 g of L-tyrosine (jet mill ground powder; average particle size, 2 - 3 μm) were weighed and mixed well in a mortar. To the triturate, 60 g of a 10% aqueous solution of hydroxypropyl cellulose and 58 g of water were added and blended well. The blend was granulated after passage through a 14-mesh sieve, dried at 60°C in a tray dryer for 3 hours, and sieved through a 10-mesh sieve. To 297 g of the granules, 3 g of magnesium stearate were added and the two were mixed well in a polyethylene bag.

The mix was charged into a single-punch tableting machine equipped with a die (10 mm \varnothing) and flat-faced punches, and compressed with a total pressure of about 2 tons to make tablets each weighing 300 mg.

The tablets had the drug release profiles shown in Fig. 6 (griseofulvin was insoluble in water, so the state of dispersion of its fine particles was evaluated by turbidity measurement). The data in Fig. 6 was obtained by conducting a release test with an apparatus of the type specified in the "Method of Disintegration Test", Japanese Pharmacopoeia, 11th rev.; 1,000 ml of distilled water was used as a testing

fluid and the glass tubes containing the test fluid were moved up and down 20 times a minute.

	Digoxin	0.25 (mg)
10	Lactose	8.75
	L-Cystine	153
	Hydroxypropyl cellulose of	
	low substitution degree	120
15	Hydroxypropyl cellulose	15
	Calcium stearate	3
	<hr/>	
20	Total	300

Digoxin (0.25 g) was dissolved in 135 g of ethanol. To the solution, 15 g of hydroxypropyl cellulose were added to make a binder solution (a film prepared by drying this solution had digoxin particles with a size of no more than 1 μ m).

25 In the next step, 8.75 g of lactose, 153 g of L-cystine and 120 g of hydroxypropyl cellulose of low substitution degree were weighed and mixed well in a mortar. To the triturate, the separately prepared binder solution was added and blended well. The blend was granulated after passage through a 14-mesh sieve, dried at 50°C in a tray dryer for 5 hours, and sieved through a 10-mesh sieve. To 297 g of the granulation, 3 g of calcium stearate were added and the two were mixed well in a polyethylene bag.

30 The mix was charged into a single-punch tableting machine equipped with a die (10 mm \varnothing) and flat-faced punches, 5 and compressed with a total pressure of about 2 tons to make tablets each weighing 300 mg.

The tablets had the dissolution profiles shown in Fig. 7 that was obtained by conducting a dissolution test with an apparatus of the type described in the "Method II (puddle method) of Dissolution Test", Japanese Pharmacopoeia, 11th rev.; 900 ml of distilled water was used as a testing fluid, and the puddle was rotated at 100 rpm.

Example 9

40

Tablet

	Indometacin	25 (mg)
45	Hydroxypropyl cellulose of	
	low substitution degree	24
	Hydroxypropyl cellulose	3
50	L-Cystine	92
	Hardened castor oil	5
	Calcium stearate	1
	<hr/>	
55	Total	150

Twenty-five grams of Indometacin (jet mill ground powder; average particle size, 6 - 7 μ m) and 24 g of hydroxypropyl cellulose of low substitution degree were weighed and mixed well in a mortar. To the

trituate. 10 g of a 10% aqueous solution of hydroxypropyl cellulose and 10 g of water were added and blended well. The blend was granulated after passage through a 24-mesh sieve, dried at 60°C in a tray dryer for 3 hours, and classified on a 20-mesh sieve. The resulting granules were designated granulation (a).

Ninety-two grams of L-cystine and 5 g of hardened castor oil were weighed and mixed well in a mortar. To the trituate, 20 g of a 10% aqueous solution of hydroxypropyl cellulose and 18 g of water were added and blended well. The blend was granulated after passage through a 24-mesh sieve, dried at 60°C in a tray dryer for 3 hours, and sieved through a 20-mesh sieve. The resulting granulation was designated granules (b).

Fifty grams of granules (a), 99 g of granules (b) and 1 g of calcium stearate were mixed well in a polyethylene bag. The mix was charged into a single-punch tableting machine equipped with a die (8 mm \varnothing) and flat-faced punches, and compressed with a total pressure of about 1.6 tons to make tablets each weighing 150 mg.

The tablets had the dissolution profiles shown in Fig. 8 that was obtained by conducting a dissolution test with an apparatus of the type specified in the "Method I (rotary basket method) of Dissolution Test", Japanese Pharmacopoeia, 11th rev.; 900 ml of Fluid 2 (pH = 6.8) was used as a testing fluid and the basket was rotated at 100 rpm.

Example 10

Capsule

Ketoprofen	75 (mg)
L-Cystine	49
L-Tyrosine	50
Stearic acid	20
Ethyl cellulose	6
Total	200

Seventy-five grams of Ketoprofen, 49 g of L-cystine (jet mill ground powder; average particle size, 3 - 4 μ m), 50 g of L-tyrosine (Jet mill ground powder; average particle size, 2 - 3 μ m) and 20 g of stearic acid (jet mill ground powder; average particle size, 5 - 6 μ m) were weighed and mixed well in a mortar. To the trituate, 60 g of a 10% solution of ethyl cellulose in ethanol were added and blended well. The blend was granulated in a rotary granulator equipped with a net (1.2 mm \varnothing), dried at 50°C in a tray dryer for 6 hours, and heated to about 80°C at which temperature the granules were kept for 15 minutes. The granules were then sieved through a 10-mesh sieve and charged into capsules in doses of 200 mg.

The capsules had the dissolution profile shown in Fig. 9 that was obtained by conducting a dissolution test with an apparatus of the type specified in "Method I (rotary basket method) of Dissolution Test", Japanese Pharmacopoeia, 11th rev.; 900 ml of Fluid 2 (pH = 6.8) was used as a testing fluid and the basket was rotated at 100 rpm.

Example 11CapsuleSpherical granules

Theophylline	100 (mg)
Lactose	7
Crystalline cellulose	40
Hydroxypropylmethyl cellulose	3
<hr/>	
Subtotal	150

Coating layer

Ethyl cellulose	22.5 (mg)
Triacetin	2.5
L-Tyrosine	25
<hr/>	
Subtotal	50

Total	200
-------	-----

A hundred grams of Theophylline, 7 g of lactose and 40 g of crystalline cellulose were weighed and mixed well in a mortar. To the triturate, 60 g of a 5% aqueous solution of hydroxypropylmethyl cellulose was added and blended well. The blend was granulated in a rotary granulator equipped with a net (1.0 mm ϕ). The granules were spheroidized with a Marumerizer machine (Model Q-236 of Fuji Powder K.K.), and dried at 60°C in a tray dryer for 3 hours.

Ethyl cellulose (22.5 g) and triacetin (2.5 g) were dissolved in ethanol (200 g), and 25 g of L-tyrosine (jet mill ground powder; average particle size; 2 - 3 μ m) were dispersed with vigorous stirring to make a coating solution.

The separately prepared spherical granules (150 g) were charged into a Flow Coater (UNI-GLATT® of Okawara Mfg. Co., Ltd.) and sprayed with 250 g of the coating solution. The spherical granules with a coating layer were charged into hard capsules in doses of 200 mg.

The capsules had the dissolution profile shown in Fig. 10 that was obtained by conducting a dissolution test with an apparatus of the type specified in "Method I (rotary basket method) of Dissolution Test", Japanese Pharmacopoeia, 11th rev.; 500 ml of distilled water was used as a testing fluid and the basket was rotated at 100 rpm.

Example 12Fine granules (per gram)

Magnesium oxide	300 (mg)
L-Cystine	320
Stearic acid	100
Crystalline cellulose	280
Total	1,000

Sixty grams of magnesium oxide, 64 g of L-cystine, 20 g of stearic acid and 56 g of crystalline cellulose were weighed and mixed well in a mortar. To the triturate, 80 g of water was added and blended well. The blend was granulated after passage through a 24-mesh sieve and the granulation was spheroidized with a Marumerizer machine (Model Q-234 of Fuji Powdal K.K.) The resulting fine granules were dried at 60°C in a tray dryer for 3 hours.

An acid control test (Fuchs test) was performed on these fine granules and the results are shown in Fig. 11.

Example 13Implant

Erythropoietin	0.016 (mg)
L-Cystine	8.984
Stearic acid	1
Total	10

In the first step, 0.16 mg of erythropoietin (freeze-dried), 89.84 mg of L-cystine and 10 mg of stearic acid were weighed and mixed well in a mortar. The triturate (10 mg) was then charged into a mold (2 mm \varnothing) and compressed with a hydraulic press with a total pressure of 200 kg. The so prepared implants were buried under the skin of rats and the time-dependent change in the count of reticulocytes relative to the erythrocytes in blood was examined. The results are shown in Fig. 12 together with comparative data for subcutaneous injection of erythropoietin in physiological saline.

Example 14Floating tablet

Oxethazaine	10 (mg)
L-Cystine	80
Stearic acid	10
Total	100

One gram of Oxethazaine, 8 g of L-cystine, 1 g of stearic acid and 5 g of dl-menthol were weighed and mixed well in a mortar. The triturate was charged into a single-punch tableting machine equipped with a die

(7 mm \varnothing) and flat-faced dies, and compressed with a total pressure of about 1.5 tons to make tablets each weighing 150 mg. The tablets were heated at 50°C under vacuum for 30 minutes to sublime dl-menthol. The tablets were further heated to 80°C to melt the stearic acid and thereafter cooled to obtain floating tablets. When thrown into water, these tablets floated on the surface of water and remained so for at least 8 hours.

Example 15

Troche

Scopolamine hydrobromide	0.2 (mg)
L-Cystine	35.8
DL-Tryptophan	30
Hardened castor oil	10
Cornstarch	3
Calcium stearate	1
<hr/>	
Total	80

Two hundred milligrams of scopolamine hydrobromide, 35.8 g of L-cystine (jet mill ground powder; average particle size, 3 - 4 μ m), 30 g of DL-tryptophan (jet mill ground powder; average particle size, 2 - 3 μ m) and 10 g of hardened castor oil (jet mill ground powder; average particle size, 3 - 4 μ m) were weighed and mixed well in a mortar. To the triturate, 30 g of a 10% cornstarch paste was added and blended well. The blend was granulated after passage through a 14-mesh sieve, dried at 50°C in a tray dryer for 5 hours, and sieved through a 10-mesh sieve. To 79 g of the granules 1 g of calcium stearate was added and the two were mixed well in a polyethylene bag.

The mix was charged into a single-punch tableting machine equipped with a die (7 mm \varnothing) and flat-faced dies, and compressed with a total pressure of about 1.5 tons to make tablets each weighing 80 mg.

The so prepared troches melted slowly in the mouth and stayed there for at least 8 hours.

Claims

1. A slow-release pharmaceutical composition which comprises at least one of the following: adenine, cystine and tyrosine in combination with at least one pharmaceutically active substance.

2. A slow-release pharmaceutical composition according to Claim 1 wherein the pharmaceutically active substance is a slightly soluble drug with a solubility of no more than 0.1%.

3. A slow-release pharmaceutical composition according to Claim 2 wherein the slightly soluble drug is in the form of particles having an average size of no more than 10 μ m.

4. A slow-release pharmaceutical composition according to Claim 3 which further contains hydroxypropyl cellulose of low substitution degree and hydroxypropyl cellulose.

5. A slow-release pharmaceutical composition according to Claim 1 which is a double-layered tablet consisting of a layer containing the pharmaceutically active substance and a layer containing no pharmaceutically active substance.

6. A slow-release pharmaceutical composition according to Claim 1 wherein a portion containing the pharmaceutically active substance is coated with a layer containing no pharmaceutically active substance.

7. A slow-release pharmaceutical composition according to Claim 1 which is a granule containing the pharmaceutically active substance.

8. A slow-release pharmaceutical composition according to Claim 1 which is an implant containing the pharmaceutically active substance.

9. A slow-release pharmaceutical composition according to Claim 1 which is in an encapsulated dosage form containing the pharmaceutically active substance.

10. A slow-release pharmaceutical composition according to Claim 1 which is a troche containing the pharmaceutically active substance.

11. Use of adenine, cystine and/or tyrosine as slow-release rendering additives in pharmaceutical compositions.
